

Single Output

HIGH RELIABILITY DC-DC CONVERTER

65-350 V **Continuous Input**

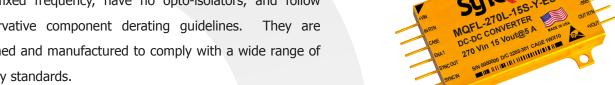

65-475 V **Transient Input** Output

5 A Output 82% @ 2.5 A /86% @ 5 A

Efficiency

Full Power Operation: -55 °C to +125 °C

The MilQor® series of high-reliability DC-DC converters brings SynQor's field proven high-efficiency synchronous rectifier technology to the Military/Aerospace industry. SynQor's innovative QorSeal® packaging approach ensures survivability in the most hostile environments. Compatible with the industry standard format, these converters operate at a fixed frequency, have no opto-isolators, and follow conservative component derating guidelines. designed and manufactured to comply with a wide range of military standards.

Design Process

MOFL series converters are:

- Designed for reliability per NAVSO-P3641-A guidelines
- Designed with components derated per:
 - MIL-HDBK-1547A
 - NAVSO P-3641A

Qualification Process

MQFL series converters are qualified to:

- MIL-STD-810F
 - consistent with RTCA/D0-160E
- SynQor's First Article Qualification
 - consistent with MIL-STD-883F
- SynQor's Long-Term Storage Survivability Qualification
- SynQor's on-going life test

In-Line Manufacturing Process

- AS9100 and ISO 9001 certified facility
- Full component traceability
- Temperature cycling
- Constant acceleration
- •24, 96, 160 hour burn-in
- Three level temperature screening

DESIGNED & MANUFACTURED IN THE USA FEATURING OORSEAL® HI-REL ASSEMBLY

Features

- Fixed switching frequency
- No opto-isolators
- Parallel operation with current share
- Remote sense
- Clock synchronization
- Primary and secondary referenced enable
- Continuous short circuit and overload protection with auto-restart feature
- Input under-voltage and over-voltage shutdown

Specification Compliance

MQFL series converters (with MQME filter) are designed to meet:

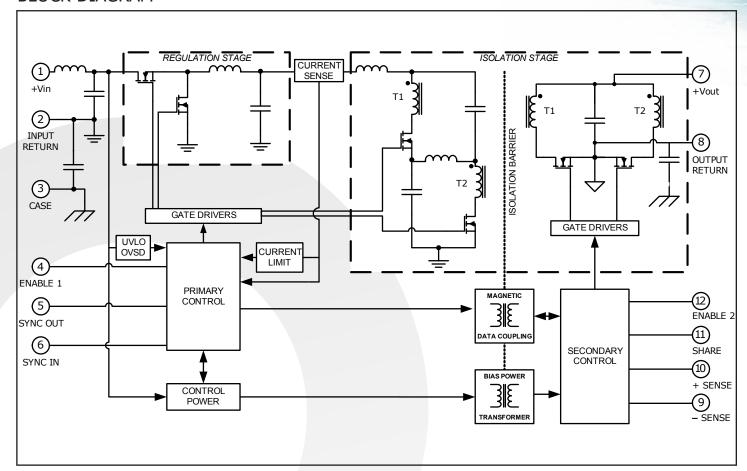

- MIL-HDBK-704-7 (A through F)
- RTCA/DO-160 Section 16, 17, 18
- MIL-STD-461 (C, D, E, F)
- RTCA/DO-160(E, F, G) Section 22

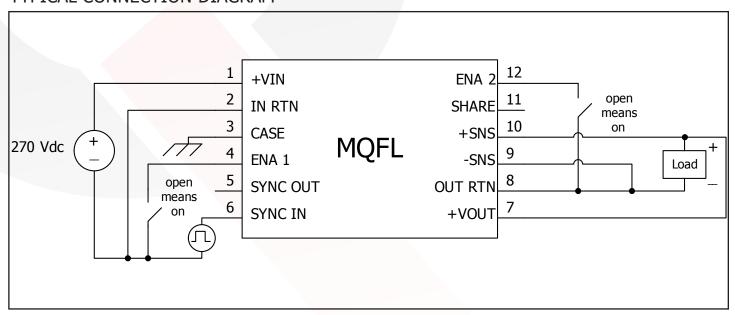

Output: 15 V

Current: 5 A

Electrical Characteristics Notes

- ${\bf 1.}\ {\bf Converter}\ {\bf will}\ {\bf undergo}\ {\bf input}\ {\bf over-voltage}\ {\bf shutdown.}$
- 2. Derate output power to 50% of rated power at Tcase = 135 °C. 135 °C is above specified operating range.
- 3. High or low state of input voltage must persist for about 200 µs to be acted on by the lockout or shutdown circuitry.
- 4. Current limit inception is defined as the point where the output voltage has dropped to 90% of its nominal value.
- 5. Parameter not tested but guaranteed to the limit specified.
- 6. Load current transition time ≥ 10 µs.
- 7. Settling time measured from start of transient to the point where the output voltage has returned to $\pm 1\%$ of its final value.
- 8. Line voltage transition time \geq 285 μ s.
- 9. Input voltage rise time \geq 285 μ s.
- 10. Operating the converter at a synchronization frequency above the free running frequency will slightly reduce the converter's efficiency and may also cause a slight reduction in the maximum output current/power available. For more information consult the factory.
- 11. After a disable or fault event, module is inhibited from restarting for 300 ms. See Shut Down section of the Control Features description.
- 12. SHARE pin outputs a power failure warning pulse during a fault condition. See Current Share section of the Control Features description.
- 13. Only the ES and HB grade products are tested at three temperatures. The C- grade products are tested at one temperature. Please refer to the Construction and Environmental Stress Screening Options table for details.
- 14. These derating curves apply for the ES and HB grade products. The C- grade product has a maximum case temperature of 70 °C and a maximum junction temperature rise of 20 °C above TCASE.
- 15. Converter delivers current into a persisting short circuit for up to 1 second. See Current Limit in the Application Notes section.
- 16. Input Over Voltage Shutdown test is run at no load, full load is beyond derating condition and could cause damage at 125 °C.
- 17. The specified operating case temperature for ES grade products is -45 °C to 100 °C. The specified operating case temperature for C- gradeproducts is 0 °C to 70 °C.

BASIC OPERATION AND FEATURES

The MQFL DC-DC converter uses a two-stage power conversion topology. The first, or regulation, stage is a buck-converter that keeps the output voltage constant over variations in line, load, and temperature. The second, or isolation, stage uses transformers to provide the functions of input/output isolation and voltage transformation to achieve the output voltage required.

Both the regulation and the isolation stages switch at a fixed frequency for predictable EMI performance. The isolation stage switches at one half the frequency of the regulation stage, but due to the push-pull nature of this stage it creates a ripple at double its switching frequency. As a result, both the input and the output of the converter have a fundamental ripple frequency of about 550 kHz in the free-running mode.

Rectification of the isolation stage's output is accomplished with synchronous rectifiers. These devices, which are MOSFETs with a very low resistance, dissipate far less energy than would Schottky diodes. This is the primary reason why the MQFL converters have such high efficiency, particularly at low output voltages.

Besides improving efficiency, the synchronous rectifiers permit operation down to zero load current. There is no longer a need for a minimum load, as is typical for converters that use diodes for rectification. The synchronous rectifiers actually permit a negative load current to flow back into the converter's output terminals if the load is a source of short or long term energy. The MQFL converters employ a "back-drive current limit" to keep this negative output terminal current small.

There is a control circuit on both the input and output sides of the MQFL converter that determines the conduction state of the power switches. These circuits communicate with each other across the isolation barrier through a magnetically coupled device. No opto-isolators are used. A separate bias supply provides power to both the input and output control circuits.

An input under-voltage lockout feature with hysteresis is provided, as well as an input over-voltage shutdown. There is also an output current limit that is nearly constant as the load impedance decreases to a short circuit (i.e., there is no fold-back or fold-forward characteristic to the output current under this condition). When a load fault is removed, the output voltage rises exponentially to its nominal value without an overshoot.

The MQFL converter's control circuit does not implement an output over-voltage limit or an over-temperature shutdown.

The following sections describe the use and operation of additional control features provided by the MQFL converter.

CONTROL FEATURES

ENABLE: The MQFL converter has two enable pins. Both must have a logic high level for the converter to be enabled. A logic low on either pin will inhibit the converter.

The ENA1 pin (pin 4) is referenced with respect to the converter's input return (pin 2). The ENA2 pin (pin 12) is referenced with respect to the converter's output return (pin 8). This permits the converter to be inhibited from either the input or the output side.

Regardless of which pin is used to inhibit the converter, the regulation and the isolation stages are turned off. However, when the converter is inhibited through the ENA1 pin, the bias supply is also turned off, whereas this supply remains on when the converter is inhibited through the ENA2 pin. A higher input standby current therefore results in the latter case.

Both enable pins are internally pulled high so that an open connection on both pins will enable the converter. Figure A shows the equivalent circuit looking into either enable pins. It is TTL compatible.

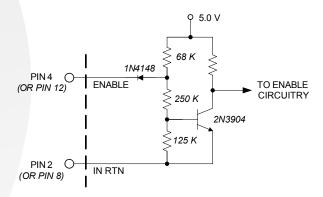

Figure A: Circuit diagram shown for reference only, actual circuit components may differ from values shown for equivalent circuit.

SHUT DOWN: The MQFL converter will shut down in response to following conditions:

- ENA1 input low
- ENA2 input low
- VIN input below under-voltage lockout threshold
- VIN input above over-voltage shutdown threshold
- Persistent current limit event lasting more than 1 second

Following a shutdown from a disable event or an input voltage fault, there is a startup inhibit delay which will prevent the converter from restarting for approximately 300 ms. After the 300 ms delay elapses, if the enable inputs are high and the input voltage is within the operating range, the converter will restart. If the VIN input is brought down to nearly 0 V and back into

Output: 15 V

Current: 5 A

the operating range, there is no startup inhibit, and the output voltage will rise according to the "Turn-On Delay, Rising Vin" specification.

Refer to the following Current Limit section for details regarding persistent current limit behavior.

REMOTE SENSE: The purpose of the remote sense pins is to correct for the voltage drop along the conductors that connect the converter's output to the load. To achieve this goal, a separate conductor should be used to connect the +SENSE pin (pin 10) directly to the positive terminal of the load, as shown in the connection diagram. Similarly, the -SENSE pin (pin 9) should be connected through a separate conductor to the return terminal of the load.

NOTE: Even if remote sensing of the load voltage is not desired, the +SENSE and the -SENSE pins must be connected to +Vout (pin 7) and OUTPUT RETURN (pin 8), respectively, to get proper regulation of the converter's output. If they are left open, the converter will have an output voltage that is approximately 200 mV higher than its specified value. If only the +SENSE pin is left open, the output voltage will be approximately 25 mV too high.

Inside the converter, +SENSE is connected to +Vout with a 100 Ω resistor and –SENSE is connected to OUTPUT RETURN with a 10 Ω resistor.

It is also important to note that when remote sense is used, the voltage across the converter's output terminals (pins 7 and 8) will be higher than the converter's nominal output voltage due to resistive drops along the connecting wires. This higher voltage at the terminals produces a greater voltage stress on the converter's internal components and may cause the converter to fail to deliver the desired output voltage at the low end of the input voltage range at the higher end of the load current and temperature range. Please consult the factory for details.

SYNCHRONIZATION: The MQFL converter's switching frequency can be synchronized to an external frequency source that is in the 500 kHz to 700 kHz range. A pulse train at the desired frequency should be applied to the SYNC IN pin (pin 6) with respect to the INPUT RETURN (pin 2). This pulse train should have a duty cycle in the 20 % to 80 % range. Its low value should be below 0.8 V to be guaranteed to be interpreted as a logic low, and its high value should be above 2.0 V to be guaranteed to be interpreted as a logic high. The transition time between the two states should be less than 300 ns.

If the MQFL converter is not to be synchronized, the SYNC IN pin should be left open circuit. The converter will then operate in its free-running mode at a frequency of approximately 550 kHz.

If, due to a fault, the SYNC IN pin is held in either a logic low or logic high state continuously, the MQFL converter will revert to its free-running frequency.

The MQFL converter also has a SYNC OUT pin (pin 5). This output can be used to drive the SYNC IN pins of as many as ten (10) other MQFL converters. The pulse train coming out of SYNC OUT has a duty cycle of 50 % and a frequency that matches the switching frequency of the converter with which it is associated. This frequency is either the free-running frequency if there is no synchronization signal at the SYNC IN pin, or the synchronization frequency if there is.

The SYNC OUT signal is available only when the DC input voltage is above approximately 125 V and when the converter is not inhibited through the ENA1 pin. An inhibit through the ENA2 pin will not turn the SYNC OUT signal off.

NOTE: An MQFL converter that has its SYNC IN pin driven by the SYNC OUT pin of a second MQFL converter will have its start of its switching cycle delayed approximately 180 degrees relative to that of the second converter.

Figure B shows the equivalent circuit looking into the SYNC IN pin. Figure C shows the equivalent circuit looking into the SYNC OUT pin.

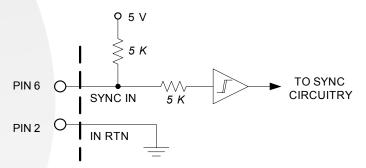

Figure B: Equivalent circuit looking into the SYNC IN pin with respect to the IN RTN (input return) pin.

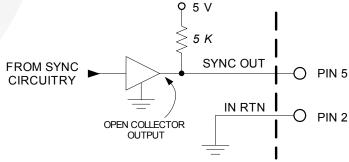

Figure C: Equivalent circuit looking into SYNC OUT pin with respect to the IN RTN (input return) pin.

Output: 15 V

Current: 5 A

CURRENT SHARE: When several MQFL converters are placed in parallel to achieve either a higher total load power or N+1 redundancy, their SHARE pins (pin 11) should be connected together. The voltage on this common SHARE node represents the average current delivered by all of the paralleled converters. Each converter monitors this average value and adjusts itself so that its output current closely matches that of the average.

Since the SHARE pin is monitored with respect to the OUTPUT RETURN (pin 8) by each converter, it is important to connect all of the converters' OUTPUT RETURN pins together through a low DC and AC impedance. When this is done correctly, the converters will deliver their appropriate fraction of the total load current to within +/- 10 % at full rated load.

Whether or not converters are paralleled, the voltage at the SHARE pin could be used to monitor the approximate average current delivered by the converter(s). A nominal voltage of 1.0 V represents zero current and a nominal voltage of 2.2 V represents the maximum rated total current, with a linear relationship in between. The internal source resistance of a converter's SHARE pin signal is 2.5 k Ω .

During an input voltage fault or primary disable event, the SHARE pin outputs a power failure warning pulse. The SHARE pin will go to 3 V for approximately 14 ms as the output voltage falls. During a current limit auto-restart event, the SHARE pin outputs a startup synchronization pulse. The SHARE pin will go to 5 V for approximately 2 ms before the converter restarts.

NOTE: Converters operating from separate input filters with reverse polarity protection (such as the MQME-270-R filter) with their outputs connected in parallel may exhibit auto-restart operation at light loads. Consult factory for details.

OUTPUT VOLTAGE TRIM: If desired, it is possible to increase the MQFL converter's output voltage above its nominal value. To do this, use the +SENSE pin (pin 10) for this trim function instead of for its normal remote sense function, as shown in

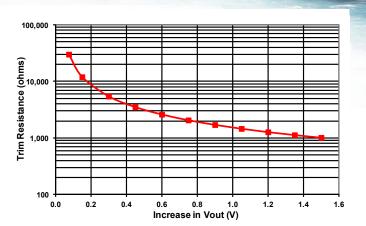

Figure E: Output Voltage Trim Graph

Figure D. In this case, a resistor connects the +SENSE pin to the -SENSE pin (which should still be connected to the output return, either remotely or locally). The value of the trim resistor should be chosen according to the following equation or from Figure E:

$$Rtrim = 100 x \frac{Vnom}{Vout - Vnom - 0.025}$$

where:

Vnom = the converter's nominal output voltage, Vout = the desired output voltage (greater than Vnom), and Rtrim is in Ohms.

As the output voltage is trimmed up, it produces a greater voltage stress on the converter's internal components and may cause the converter to fail to deliver the desired output voltage at the low end of the input voltage range at the higher end of the load current and temperature range. Please consult the factory for details.

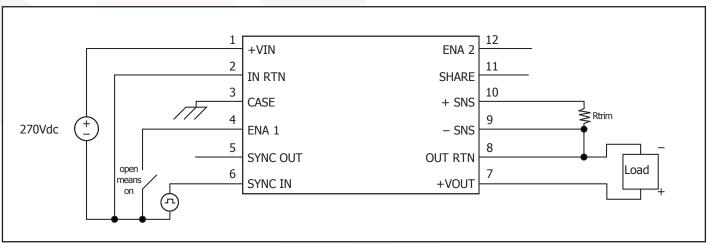

Figure D: Typical connection for output voltage trimming.

INPUT UNDER-VOLTAGE LOCKOUT: The MQFL converter has an under-voltage lockout feature that ensures the converter will be off if the input voltage is too low. The threshold of input voltage at which the converter will turn on is higher that the threshold at which it will turn off. In addition, the MQFL converter will not respond to a state of the input voltage unless it has remained in that state for more than about 200 µs. This hysteresis and the delay ensure proper operation when the source impedance is high or in a noisy environment.

INPUT OVER-VOLTAGE SHUTDOWN: The MQFL converter also has an over-voltage feature that ensures the converter will be off if the input voltage is too high. It also has a hysteresis and time delay to ensure proper operation.

CURRENT LIMIT: The converter will reduce its output voltage in response to an overload condition. If the output voltage drops to below approximately 50 % of the nominal setpoint for longer than 1 second, the auto-restart feature will engage. The auto-restart feature will stop the converter from delivering load current, in order to protect the converter and the load from thermal damage. After four seconds have elapsed, the converter will automatically restart.

In a system with multiple converters configured for load sharing using the SHARE pin, if the auto-restart feature engages, the converters will synchronize their restart using signals communicated on the SHARE pin.

BACK-DRIVE CURRENT LIMIT: Converters that use MOSFETs as synchronous rectifiers are capable of drawing a negative current from the load if the load is a source of short- or long-term energy. This negative current is referred to as a "back-drive current".

Conditions where back-drive current might occur include paralleled converters that do not employ current sharing, or where the current share feature does not adequately ensure sharing during the startup or shutdown transitions. It can also occur when converters having different output voltages are connected together through either explicit or parasitic diodes that, while normally off, become conductive during startup or shutdown. Finally, some loads, such as motors, can return energy to their power rail. Even a load capacitor is a source of back-drive energy for some period of time during a shutdown transient.

To avoid any problems that might arise due to back-drive current, the MQFL converters limit the negative current that the converter can draw from its output terminals. The threshold for this back-drive current limit is placed sufficiently below zero so that the converter may operate properly down to zero load, but its absolute value (see the Electrical Characteristics page) is small compared to the converter's rated output current.

THERMAL CONSIDERATIONS: The suggested Power Derating Curves for this converter as a function of the case temperature and the maximum desired power MOSFET junction temperature on the figures page. All other components within the converter are cooler than its hottest MOSFET, which at full power is no more than 20 °C higher than the case temperature directly below this MOSFET. The Mil-HDBK-1547A component derating guideline calls for a maximum component temperature of 105 °C. The power derating figure; therefore has one power derating curve that ensures this limit is maintained. It has been SynQor's extensive experience that reliable long-term converter operation can be achieved with a maximum component temperature of 125 °C. In extreme cases, a maximum temperature of 145 °C is permissible, but not recommended for long-term operation where high reliability is required. Derating curves for these higher temperature limits are also included in Figure 5. The maximum case temperature at which the converter should be operated is 135 °C.

When the converter is mounted on a metal plate, the plate will help to make the converter's case bottom a uniform temperature. How well it does so depends on the thickness of the plate and on the thermal conductance of the interface layer (e.g. thermal grease, thermal pad, etc.) between the case and the plate. Unless this is done very well, it is important not to mistake the plate's temperature for the maximum case temperature. It is easy for them to be as much as 5-10 °C different at full power and at high temperatures. It is suggested that a thermocouple be attached directly to the converter's case through a small hole in the plate when investigating how hot the converter is getting. Care must also be made to ensure that there is not a large thermal resistance between the thermocouple and the case due to whatever adhesive might be used to hold the thermocouple in place.

INPUT SYSTEM INSTABILITY: This condition can occur because any DC-DC converter appears incrementally as a negative resistance load. A detailed application note titled "Input System Instability" is available on the SynQor website which provides an understanding of why this instability arises, and shows the preferred solution for correcting it.

MilQor® Hi-Rel converters and filters are offered in three variations of environmental stress screening options. All ES-Grade and HB-Grade MilQor Hi-Rel converters use SynQor's proprietary QorSeal® Hi-Rel assembly process that includes a Parylene-C coating of the circuit, a high performance thermal compound filler, and a nickel barrier gold plated aluminum case. Each successively higher grade has more stringent mechanical and electrical testing, as well as a longer burn-in cycle. The ES- and HB-Grades are also constructed of components that have been procured through an element evaluation process that pre-qualifies each new batch of devices.

Shock	516.5 - Procedure I	20 g peak, 11 ms, Functional Shock (Operating no load) (saw tooth)				
SHOCK	516.5 - Procedure VI	Bench Handling Shock				
Sinusoidal vibration	514.5 - Category 14	Rotary wing aircraft - helicopter, 4 hrs/axis, 20 g (sine sweep from 10 - 500 Hz)				
Sand and Dust	510.4 - Procedure I	Blowing Dust				
Saliu aliu Dust	510.4 - Procedure II	Blowing Sand				

Output: 15 V

Current: 5 A

First Article Testing consistent with MIL-STD-883F

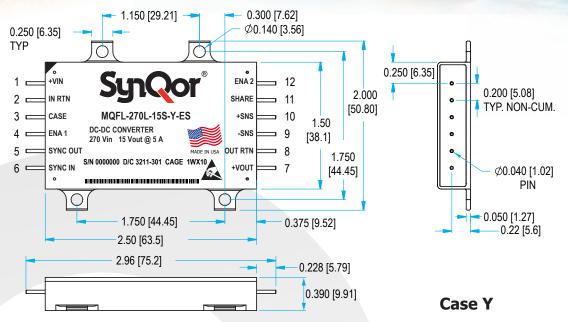

First Article Testing Consistent With Mile-STD-883F								
MIL-STD-883F Test	Method	Description						
Electrical Tests	5005							
Physical Dimensions test	2016							
Resistance to Solvents test	2015.13							
Solderability test	2003.8							
Lead Integrity test	2004.5							
Salt Atmosphere test	1009.8	Condition "A"						
Adhesion of Lead Finish test	2025.4							
Altitude Operation test	1001	Condition "C"						
ESD Sensitivity	3015.7	Class 2						
Stabilization Bake test	1008.2	Condition "C"						
Vibration Fatigue test	2005.2	Condition "A"						
Random Vibration test	2026	Condition "II K"						
Sequential Test Group #1								
Life Test – Steady State test	1005.8							
Life Test – Intermittent Duty test	1006							
Sequential Test Group #2								
Temperature Cycle test	1010.8	Condition "C"						
Constant Acceleration test	2001.2	Condition "A"						
Sequential Test Group #3								
Thermal Shock test	1011.9	Condition "B"						
Temperature Cycle test	1010.8	Condition "C"						
Moisture Resistance test	1004.7	With Sub cycle						
Sequential Test Group #4								
Mechanical Shock test	2002.4	Condition "B"						
Variable Frequency Vibration test	2007.3	Condition "A"						

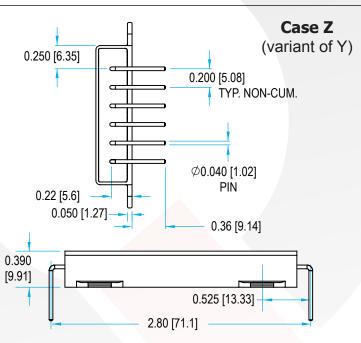

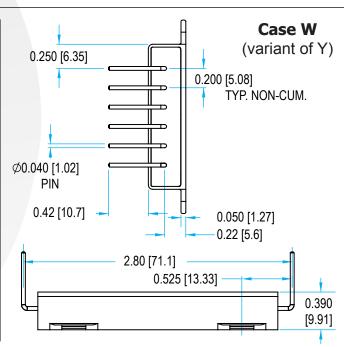

Output: 15 V

Current: 5 A

Mechanical Diagrams

NOTES

- 1) Pins 0.040" (1.02 mm) diameter
- 2) Pin Material: Copper Alloy
- Finish: Gold over Nickel plating, followed by Sn/Pb solder dip

 3) All dimensions in inches (mm) Tolerances: x.xx +/-0.02 in. (x.x +/-0.5 mm)
- 3) All dimensions in inches (mm) Tolerances: x.xx +/-0.02 in. (x.x +/-0.5 mm) x.xxx +/-0.010 in. (x.xx +/-0.25 mm)
- 4) Weight: 2.8 oz (78.5 g) typical
- 5) Workmanship: Meets or exceeds IPC-A-610 Class III
- 6) Print Labeling on Top Surface per Product Label Format Drawing
- 7) Pin 1 identification hole, not intended for mounting (case X and U)
- 8) Baseplate flatness tolerance is 0.004'' (.10 mm) TIR for surface.

PIN DESIGNATIONS

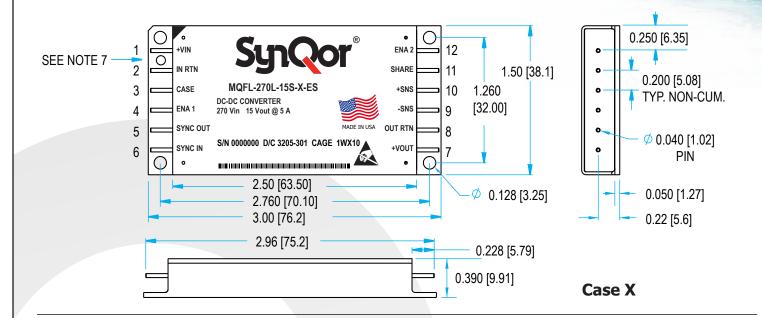

Pin #	Function
1	Positive input
2	Input return
3	Case
4	Enable 1
5	Sync output
6	Sync input

MilQor Converter FAMILY MATRIX

The tables below show the array of MilQor converters available. When ordering SynQor converters, please ensure that you use the complete part number according to the table in the last page. Contact the factory for other requirements.

		Single Output										Dua	l Outp	ud †
	1.5 V	1.8 V	2.5 V	3.3 V	5 V	6 V	7.5 V	9 V	12 V	15 V	28 V	5 V	12 V	15 V

Check with factory for availability.

^{†80%} of total output current available on any one output.
*Converters may be operated at the highest transient input voltage, but some component electrical and thermal stresses would be beyond MIL-HDBK-1547A guidelines.

Output: 15 V

Current: 5 A

PART NUMBERING SYSTEM

The part numbering system for SynQor's MilQor DC-DC converters follows the format shown in the table below.

Not all combinations make valid part numbers, please contact SynQor for availability. See the Product Summary web page for more options.

Example: MQFL-270L-15S-Y-ES

Model	Input	Output V	/oltage(s)	Package Outline/	Screening	
Name	Voltage Range	Single Output	Dual Output	Pin Configuration	Grade	
MQFL MQHL MQHR	28 28E 28V 28VE 270 270L	1R5S 1R8S 2R5S 3R3S 05S 06S 6R5S 7R5S 08S 09S 12S 15S 28S	05D 6R5D 12D 15D	U X Y W Z	C ES HB	

APPLICATION NOTES

A variety of application notes and technical white papers can be downloaded in pdf format from the SynQor website.

Contact SynQor for further information and to order:

Phone: 978-849-0600 Toll Free: 1-888-567-9596 Fax: 978-849-0602

USA

PATENTS

SynQor holds numerous U.S. patents, one or more of which apply to most of its power conversion products. Any that apply to the product(s) listed in this document are identified by markings on the product(s) or on internal components of the product(s) in accordance with U.S. patent laws. SynQor's patents include the following:

7,050,309 7,765,687 7,787,261

8,149,597 8,644,027

Warranty

SynQor offers a two (2) year limited warranty. Complete warranty information is listed on our website or is available upon request from SynQor.
